Problem 5

Let $A = k[x, y, z]/(x^2y^2z^2, x^3y^2z)$. We wish to compute the dimension of A at the maximal ideal (x, y, z). Since $x^2y^2z^2$ is a nonzerodivisor in $k[x, y, z]_{(x,y,z)}$, quotienting out by it yields a ring with dimension two (by lemma 46). Next note that after quotienting out by x^3y^2z we still have a chain of primes $(x) \subset (x, y) \subset (x, y, z)$ where the inclusions are still proper (we can't get a z in (x, y) for example, because all we can do with $x^2y^2z^2$ is dock powers) and hence the dimension is two.

Problem 6

Let $A = k[x, y, z]/(x^3 - y^2, x^5 - z^2, y^5 - z^3)$. We wish to compute the dimension of A at (x, y, z). Consider first quotienting by $x^3 - y^2$, which is clearly prime (and a nonzerodivisor), and hence yields a domain, docking the dimension from 3 to 2. Next consider quotienting by $x^5 - z^2$, which is no longer prime, but is still a nonzerodivisor and hence yields a ring of dimension 1. Now if we quotient out the last generator, we obtain a ring in which

Problem 7

Let k be a field. Let $f \in k[x, y]$ be a polynomial and $a, b \in k$ be elements such that $f(a, b) = 0$. Let $\mathfrak{m} = (x - a, y - b)$ be the corresponding maximal ideal in the ring $A = k[x, y]/(f)$. By construction, $A_\mathfrak{m}$ is a local ring. We wish to check that it is regular, i.e. that the maximal ideal has exactly $\dim A_\mathfrak{m} = 1$ generators. The number of generators is given by $\dim_{A/\mathfrak{m}} \mathfrak{m}/\mathfrak{m}^2 = \dim_k \mathfrak{m}/\mathfrak{m}^2$. In this case it's clear that $\mathfrak{m}$ is the ideal of all polynomials with root at (a, b), i.e. every element of $\mathfrak{m}$ has a finite Taylor series about (a, b) given by $\sum_{i+j\geq 1} c_{ij}(x - a)^i(y - b)^j$ for $c_{ij} \in k$. The finiteness is obvious since we are simply dealing with polynomials. It follows, then, that elements of $\mathfrak{m}^2$ look like $\sum_{i+j\geq 2} d_{ij}(x - a)^i(y - b)^j$ for $d_{ij} \in k$, as we have squared away linear terms. The quotient $\mathfrak{m}/\mathfrak{m}^2$ is then composed of elements of the form $c_{10}(x - a) + c_{01}(y - b)$, which is 2-dimensional as a vector space and isomorphic to k^2; we must be careful to note, however that (f) is zero in our original ring and hence its image in $\mathfrak{m}/\mathfrak{m}^2$, $(\partial_x f(a, b)(x - a) + \partial_y f(a, b)(y - b))$ must also be zero, which is a dimension one subspace. Hence we see that the dimension of $\mathfrak{m}/\mathfrak{m}^2$ must be $2 - 1 = 1$, as desired.

Problem 9

Consider $f = xy^2 + x^2y = xy(y + x)$, which has zeros at $x = y = 0$ and at $x = y$. We compute $\partial_x f = y^2 + 2xy$ and $\partial_y f = 2yx + x^2$; the only singular point, then, is $(0, 0)$. Next consider $f = x^2 - 2x + y^3 - 3y^2 + 3y$; we compute $\partial_x f = 2x - 2$ and $\partial y f = 3y^2 - 6y + 3 = 3(y - 1)^2$. The singular point is then $(1, 1)$, as $f(1, 1) = 0$. Finally, consider $f = x^n + y^n + 1$, which has

$\partial_x f = nx^{n-1}, \partial_y f = ny^{n-1}$. These derivatives are never zero except at $(0,0)$, which is not a root of f, and hence f has no singular points.

Problem 10

Let k an algebraically closed field. Let $f \in k[x,y]$ be a squarefree polynomial of degree 1. In other words, $f = ax + by + c$. Clearly f can only have singular points if it is a constant, which contradicts the degree being 1, and hence has no singular points. Next consider degree 2: $f = ax^2 + bxy + cy^2 + dx + ey + f$. In this case, solving for the singular points involves simultaneously solving a linear system, which yields a single point. We can assume that the system is non-degenerate because of the squarefree condition; if it were, it is straightforward but tedious to show that f can then be written as $(\sqrt{a}x \pm \sqrt{b}y + d/2)^2$, a square. Finally, we want our singular point to land on the curve - this can always be done by adjusting f.

For degree 3, we solve two quadratics, and hence we expect 4 singular points, and again, not an infinite number due to the squarefree condition. In this way, we might guess that in general for degree d we have, at maximum, $(d-1)^2$ singular points.
